# **Geochemical monitoring during CO<sub>2</sub> EOR – applications to CCS MMV**

**Ernie Perkins**

# PENNWEST RESEARCH PROGRAM

Initiated in 2004, the research program focussed on 8 areas:

- Geology and Hydrogeology,
- CO2 Leakage Potential,
- Environmental Monitoring,
- Geophysical Monitoring,
- Geomechanical Issues,
- Geochemical Monitoring and **Geochemical Modelling**
- Reservoir modelling.

The **Geochemical Modelling** project used detailed geological information, mineralogical data, produced and injected fluid compositional data, field operational parameters and production data, and reservoir model simulations provided by other researchers in the program and by the operators.

A typical summer day

# PENNWEST RESEARCH PROGRAM

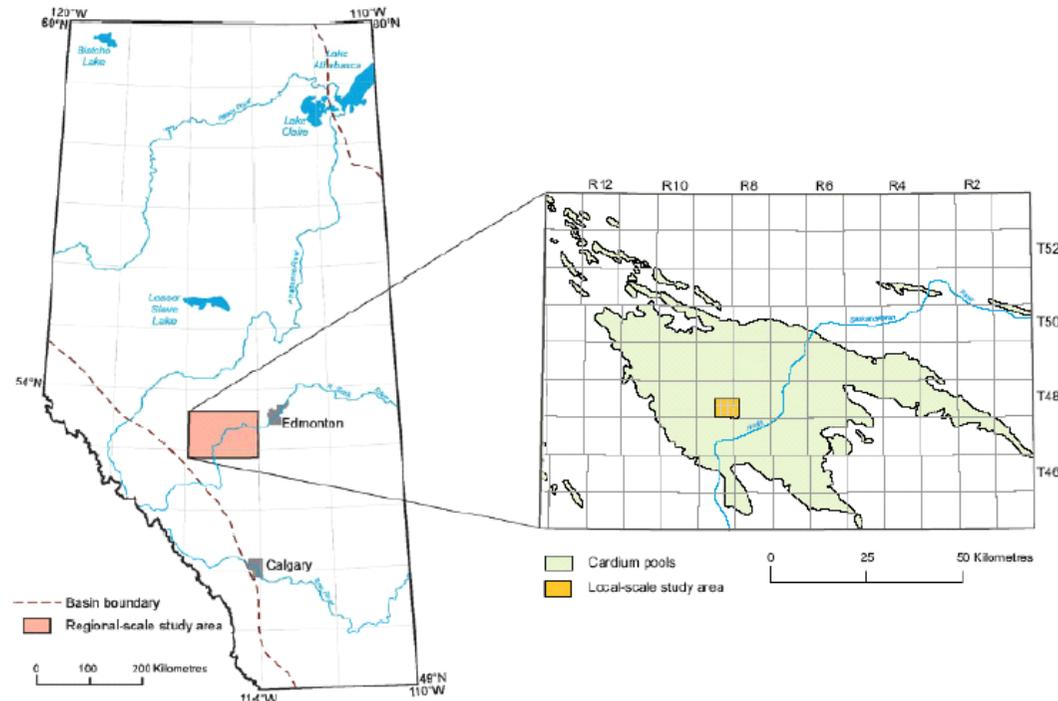

The research program was lead by The Alberta Research Program, now named Alberta Innovates – Technology Futures.

The geochemical research shown in the following presentation was largely undertaken by S. Talman, M. Shevalier, M. Nightingale and E. Perkins.

Research in other areas was the responsibility of numerous other researchers, technologists and field operators – we thank them for the use of their results.

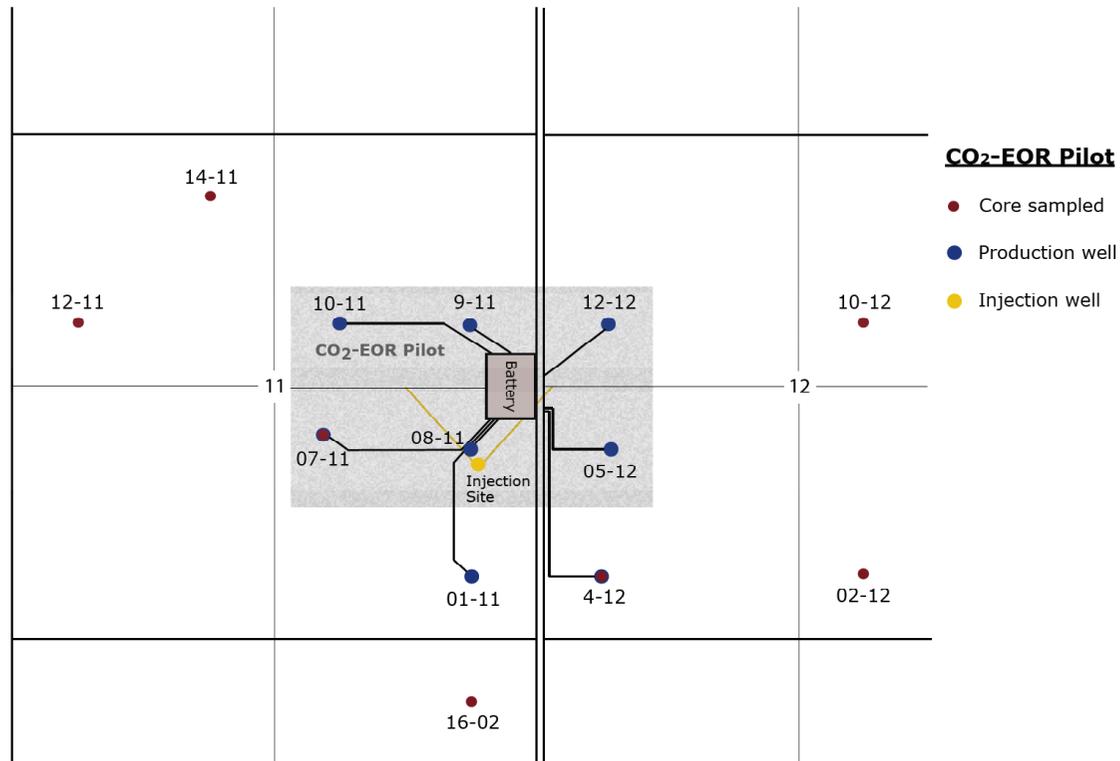

# PENN WEST SITE HISTORY

- Discovered in 1953.
- Approximate area is 140,000 km<sup>2</sup>.
- Average thickness: 20 m.
- Primary production begins in 1955 from the Cardium formation.
- Water flood begins in 1958.

The Cretaceous Cardium formation consists of stacked sandstone sheets with interstitial shale beds. Unit is capped by the Wapiabi Shale formation and underlain by the Blackstone Shale formation. Initial reservoir temperature and pressure estimated to be 50 °C and 19 MPa.

# PENN WEST CO<sub>2</sub>-EOR SITE

Wells at 10-11 and 8-11 are historic water injectors.

Well 7-11 was converted to observation/downhole sampling well.

- 2005: CO<sub>2</sub> miscible flood in 2 five spot pattern. Water support used.
- 2007: Converted to WAG operations. Wells switched on monthly basis
- Variable CO<sub>2</sub> source.

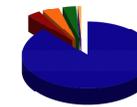

# SELECTED PORTION OF FLUID MONITORING CHEMISTRY

On a monthly basis, subject to operational constraints,

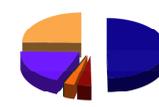

- Production fluid samples taken and analysed,
- Injection stream samples taken and analysed.

# WATER FLOOD CHEMISTRY: SAMPLING VERSUS MODELLING

Sample: MNPW16

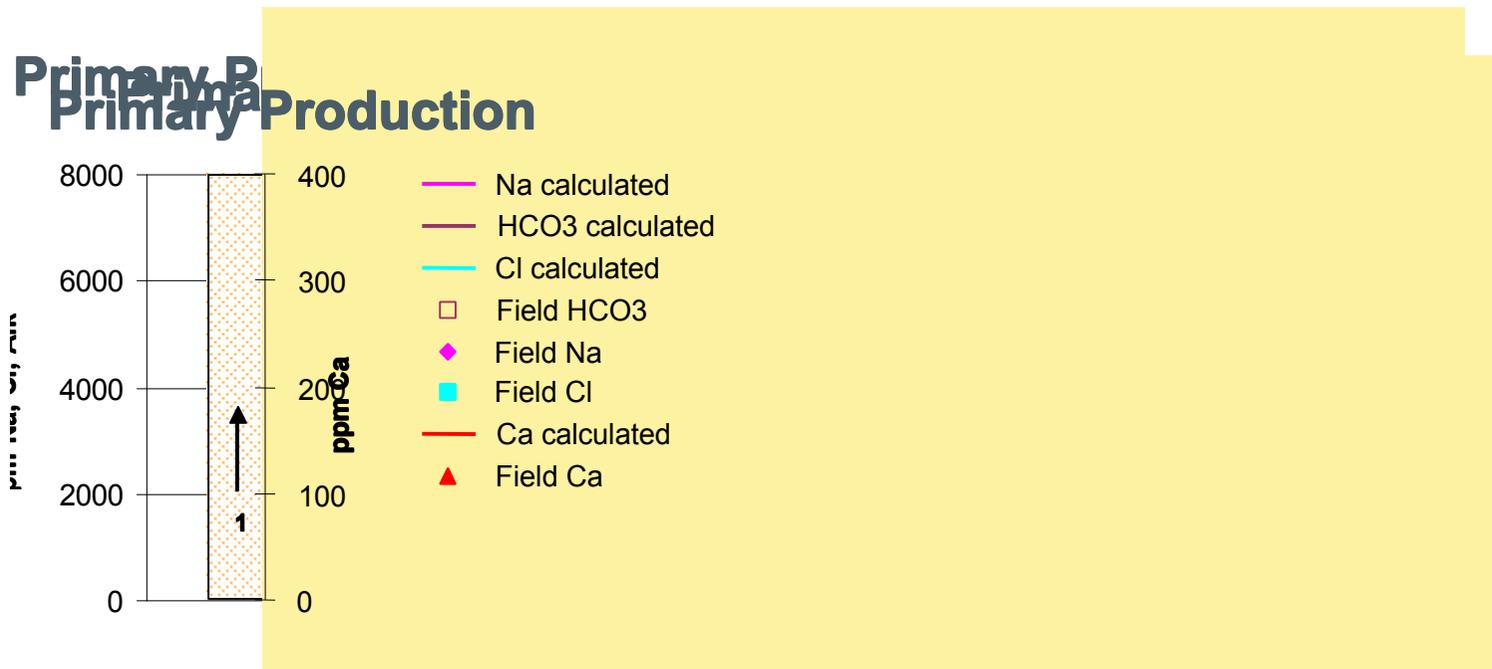

Sample: MNPW15

Geochemical modelling included the effects of supercritical gas, fluid mixing, dissolution, precipitation, ion exchange and gas solubility in oil.

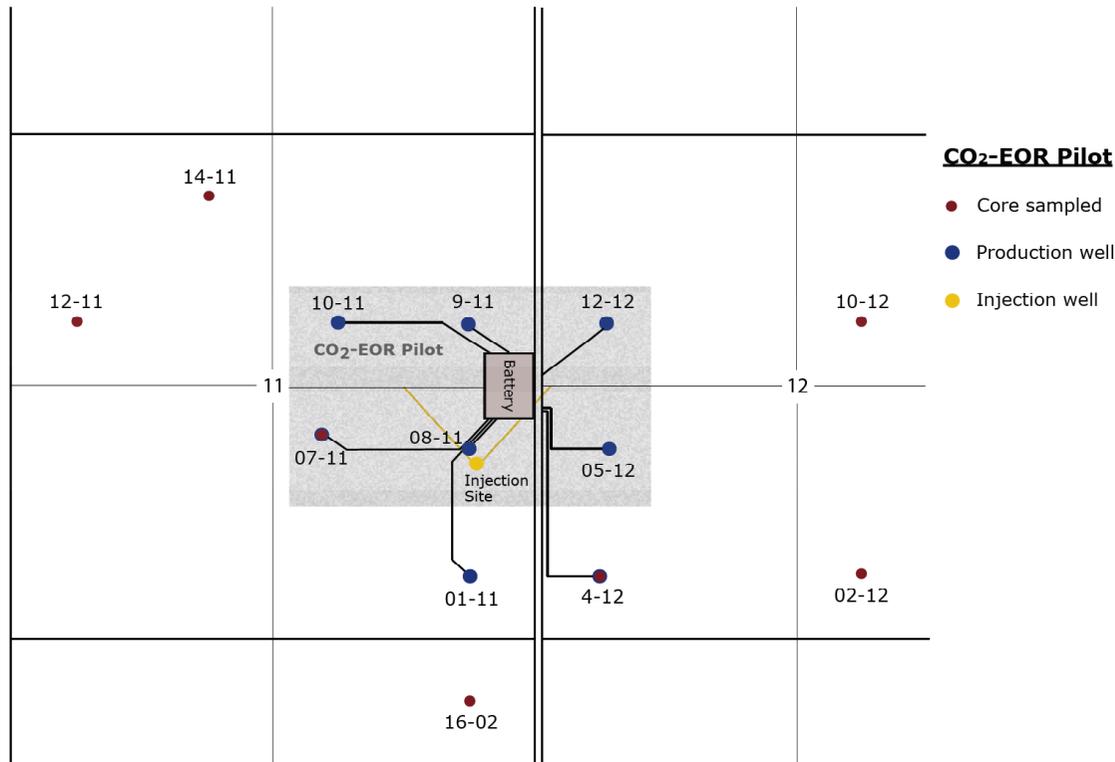

There is a good correlation between historical and predicted values, but not between baseline and predicted values. This is due to operational changes; different make-up water and the increasing use of re-cycled waters.

# 1-D COUPLED GEOCHEMICAL FLOW SIMULATION

Similar to the previous conclusion, the differences between modelled and the measured fluid composition is due to changing make-up water sources and the increasing use of re-cycled waters.

# FLUID SAMPLING LOCATIONS

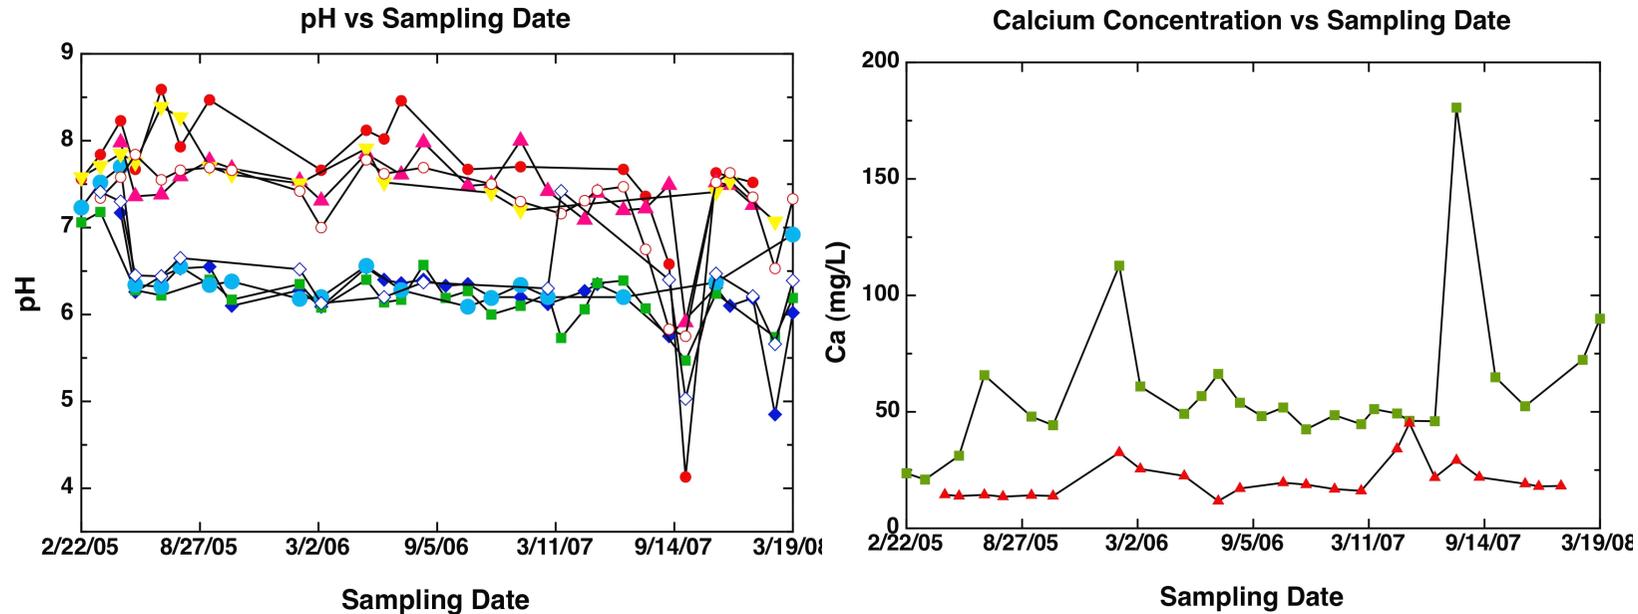

Wells 10-11 and 8-11 have been historically used as water injectors, but are now production wells.

Samples were taken from the production wells around each of the injection wells in the 5 spot pattern.

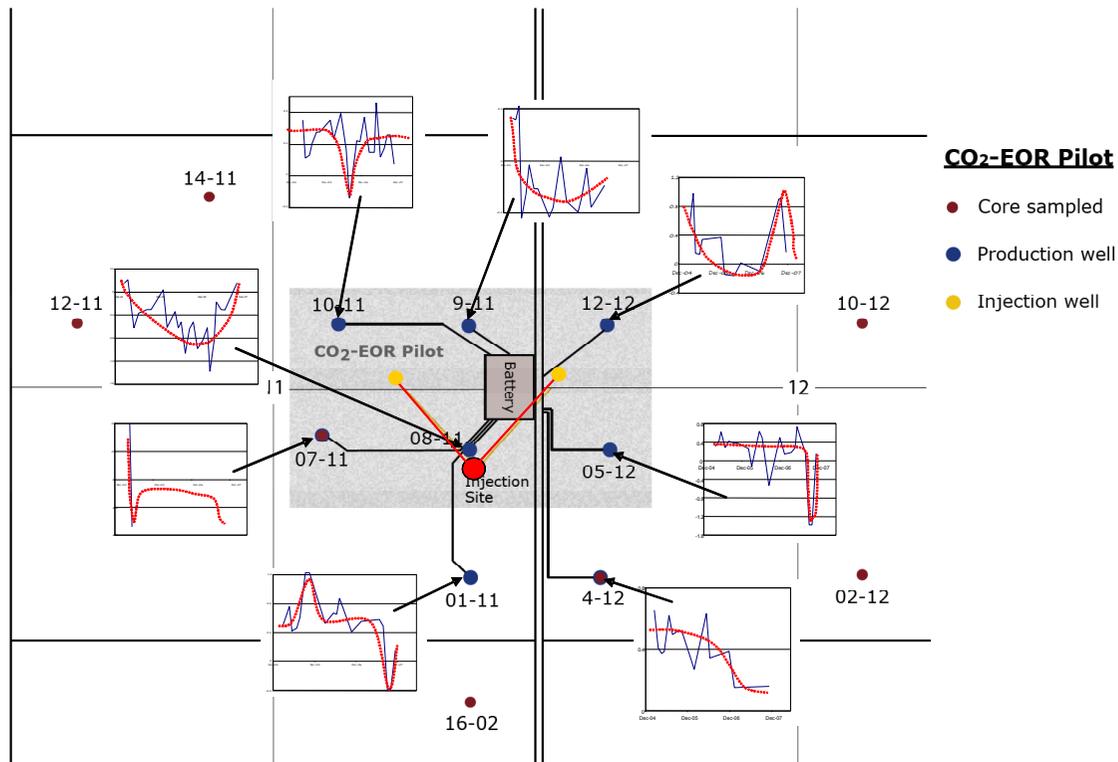

- The saturation indices of carbonate minerals were calculated for each sample, and examined as a function of time for each well.

# WELL WORK OVER EFFECTS

- The effects of workover fluids can be clearly seen in the spikes of calcium concentration, and to a lesser extent, changes in pH.

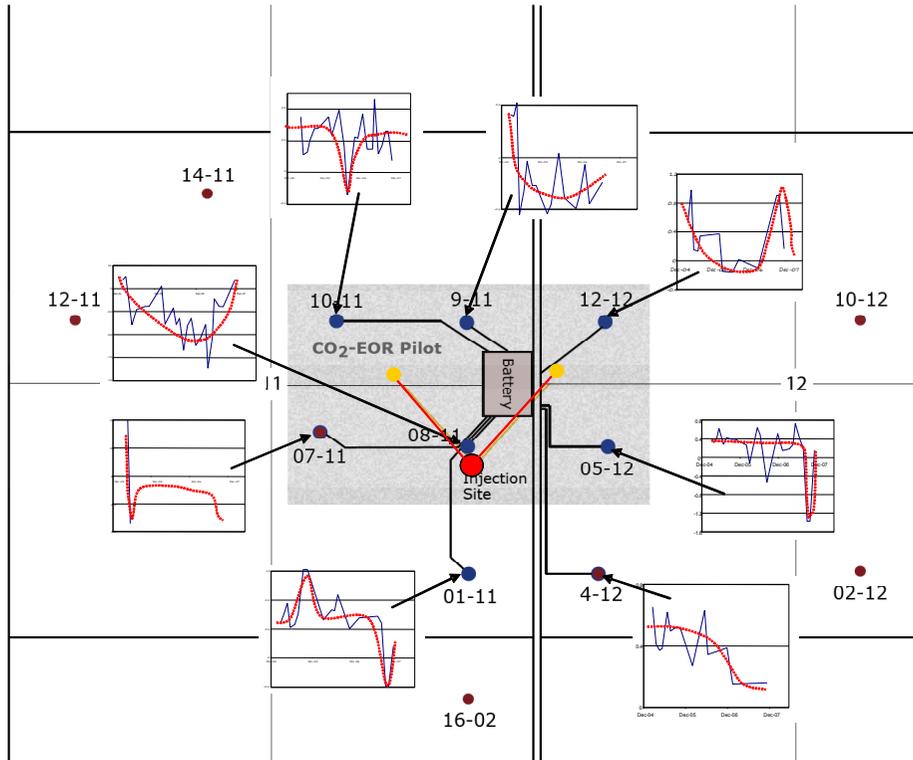

# CALCULATED CALCITE SI'S AS A FUNCTION OF TIME FOR EACH WELL

## *The Observations*

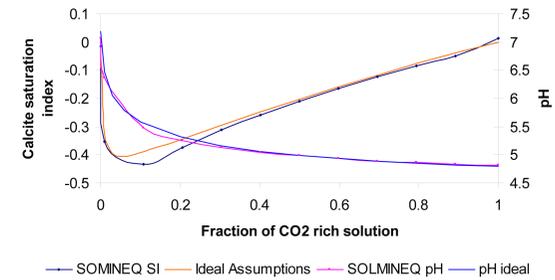

- The calcite SI's change significantly with time.
- All are undersaturated significantly for some period of time.
- Fact: the reservoir contains significant amounts of carbonate minerals!
- “On trend” wells behaved quite differently than “Off trend” wells

# CALCULATED CALCITE SI'S AS A FUNCTION OF TIME FOR EACH WELL

## CO<sub>2</sub>-EOR Pilot

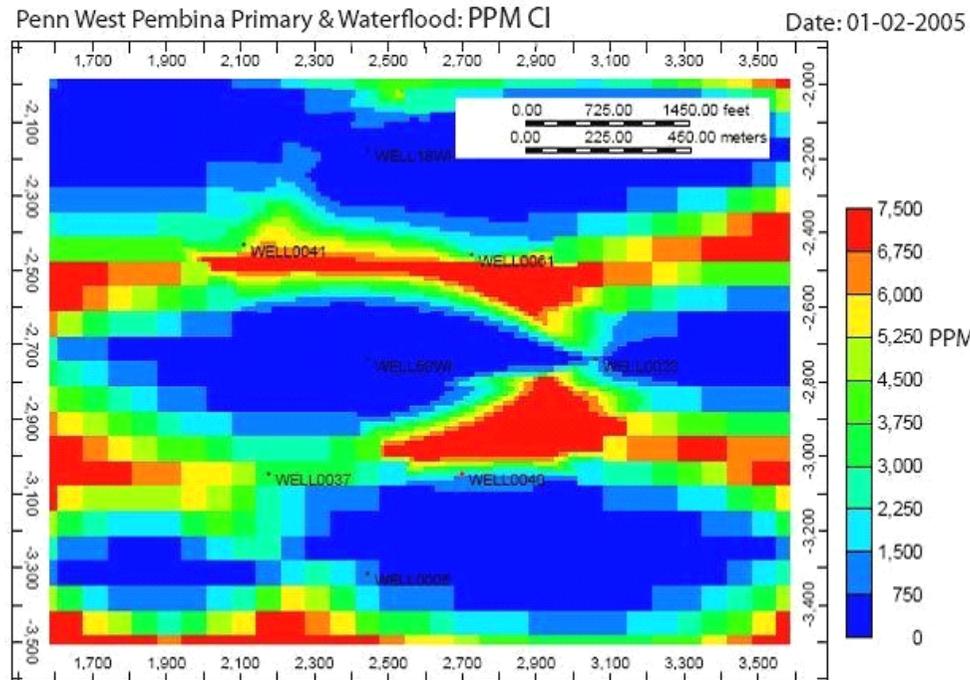

- Core sampled
- Production well
- Injection well

## *The Conclusions*

- The calcite undersaturation is the results of different fluids (waters) mixing, one in equilibrium with the supercritical CO<sub>2</sub> plume and one not.
- “On trend” wells responded quickly to breakthrough.
- “Off trend” wells responded slowly.

# 3-D COUPLED GEOCHEMISTRY AND RESERVOIR MODELLING –END OF WATER FLOOD

## *Chloride concentration in the reservoir.*

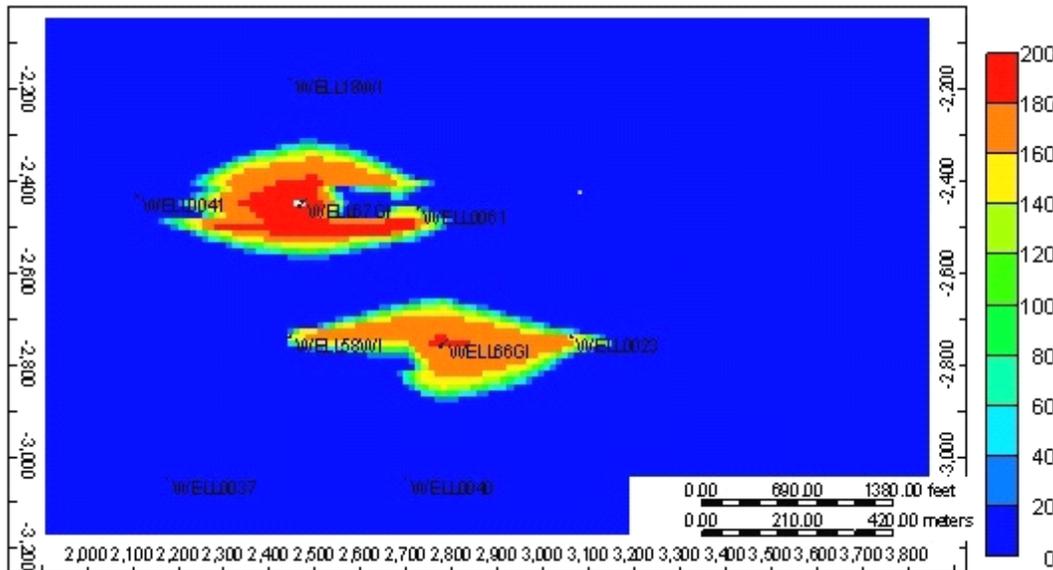

- Modelled using CMG GHG GEM
- 3<sup>rd</sup> layer in reservoir
- At the end of waterflood

*Display is rotated from earlier pattern description.*

### Conclusions:

- Fracture pattern in the reservoir controls water movement.
- Good match on all dissolved components.

# 3-D COUPLED GEOCHEMISTRY AND RESERVOIR MODELLING –THE CO<sub>2</sub> FLOOD

## *Partial Pressure of CO<sub>2</sub> fluid in the reservoir.*

- Modelled using CMG GHG GEM
- 3<sup>rd</sup> layer in reservoir
- 18 months after CO<sub>2</sub> injection began.

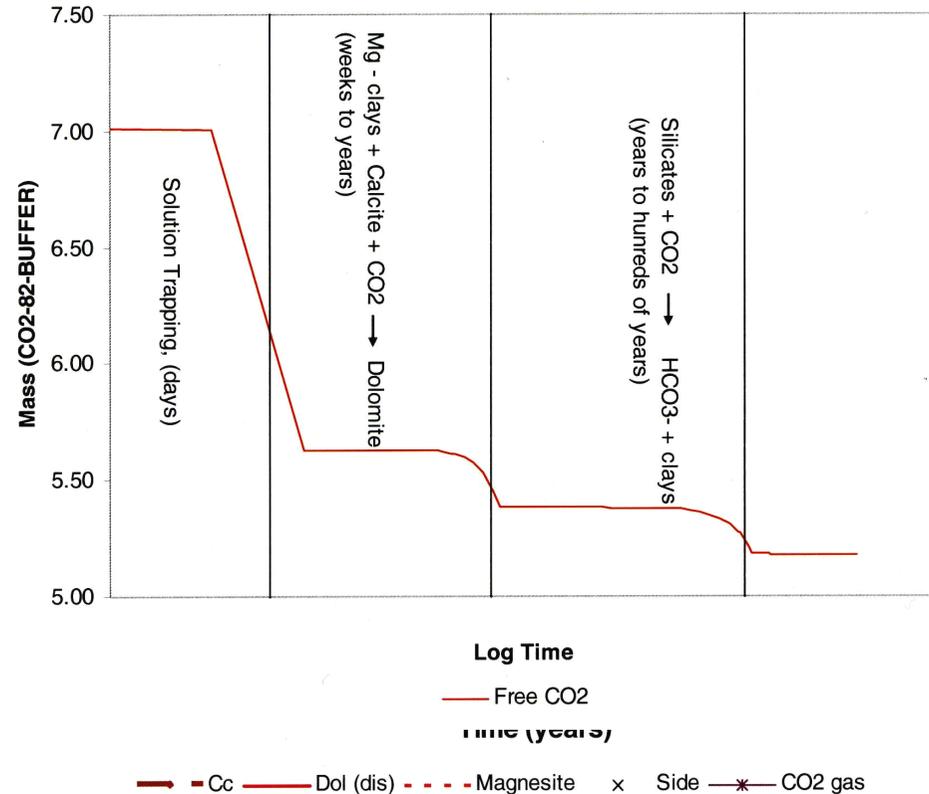

*Display is rotated from earlier pattern description.*

## Conclusions:

- Fracture pattern in the reservoir controls CO<sub>2</sub> and water movement.
- All components behaved in a complimentary fashion.
- As observed previously, modelled concentrations were off-set from analytical values.

# DETAILED REACTION PATH MODELLING

- Impacts of changing
  - thermodynamic data
  - fluid chemistry
  - mineralogy
  - chemical processes
- were evaluated.

Calculations shown for the Cemented Cardium Sandstone.

# CONCLUSIONS - TRAPPING

| CO <sub>2</sub> trapping mechanisms    | Unit                        |              |              |                    |
|--|-----------------------------|--------------|--------------|--------------------|
|  | kg/m <sup>3</sup> reservoir | Sandstone    | Conglomerate | Interstitial Shale |
| CO <sub>2</sub> Dissolved in Oil       | 1.27                        | 0.59         | 0.79         | 0.95               |
| CO <sub>2</sub> Residual Gas           | 26.12                       | 12.53        | 14.47        | 18.47              |
| CO <sub>2</sub> Solution Trapping      | 5.50                        | 2.55         | 3.44         | 4.13               |

| CO <sub>2</sub> Mineralogical Trapping | 0.47                        | 0.08         | 1.31         | 0.59               |
| <b>Total CO<sub>2</sub> Trapped</b>    | <b>34.79</b>                | <b>16.09</b> | <b>21.74</b> | <b>26.09</b>       |

# CONCLUSIONS – EOR

- Fluid sampling programs during CO<sub>2</sub> EOR are appropriate to “*chemically*” evaluate the reservoir. The results are necessary input to more numerically complex simulations.
- Coupled 3-D geochemical – flow models are necessary to totally represent the “*physical*” reservoir processes and the coupling to the chemical processes.

# CONCLUSIONS - CCS

- *EOR fluid and mineralogical sampling programs allow CO<sub>2</sub> storage amounts to be determined.*
- *EOR fluid sampling program allow the ionic concentration and its variation in fluid chemistry to be quantified for monitoring purposes.*
- *Coupled geochemical – reservoir simulators allow long term fate of CO<sub>2</sub> in the reservoir to be determined.*

The top portion of the image features four horizontal, wavy white lines on a dark blue background, creating a decorative header effect.
