Geological Storage Options for CO₂

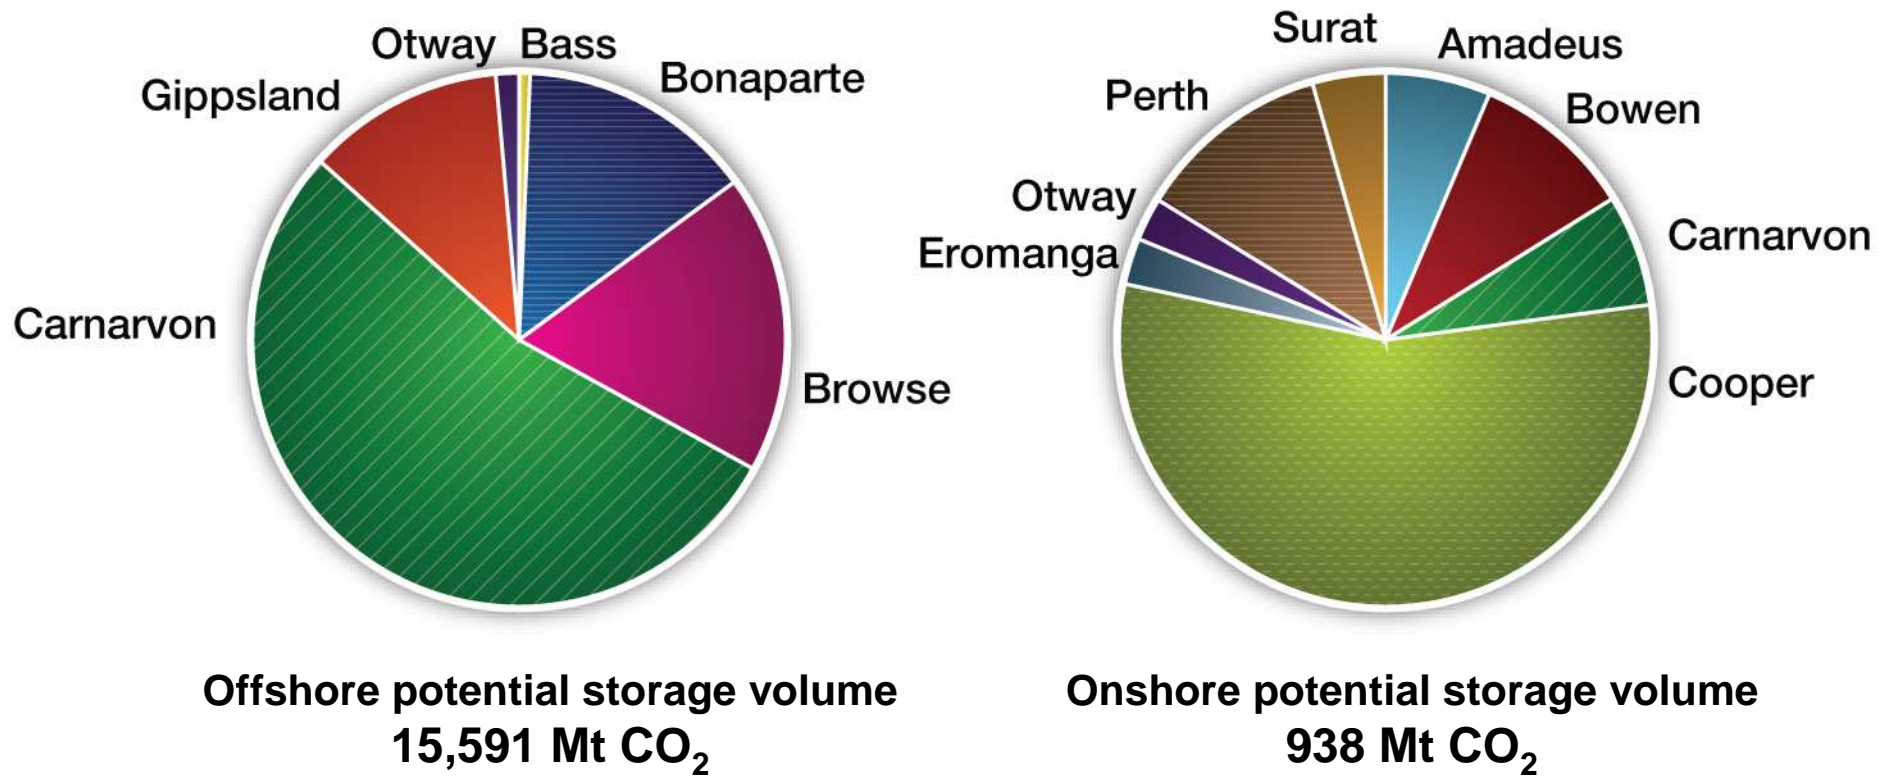

- 1 Depleted oil and gas reservoirs
- 2 Use of CO₂ in enhanced oil recovery
- 3 Deep unused saline water-saturated reservoir rocks
- 4 Deep unmineable coal seams
- 5 Use of CO₂ in enhanced coal bed methane recovery
- 6 Other suggested options (basalts, oil shales, cavities)

Basalts, Salt, Cavities

CO₂ Storage potential in Australia's oil and gas reservoirs

Storage potential in worldwide gas reservoirs

Globally, conventional gas reserves are 180 trillion m³ and resources 210 trillion m³ (BP Statistical Review, 2009). Using Otway results of a 'replacement' efficiency of 60% (% of pore space available for CO₂ storage following gas production) suggests a global potential storage capacity of up to 700 Gigatonnes CO₂!

700 Gt CO₂ Storage: implications for global CCS

Whilst much of this storage capacity may not be accessible for technical or economic reasons, it is equivalent to more than 60 years of total global stationary emissions, suggesting that not only is gas a lower carbon fuel, but also storage in depleted gas fields may have a major role in decreasing global CO₂ emissions.

EOR

- What is EOR
- How significant is EOR
- CO₂ Displacement Process
- Field Injection Options

China Australia Geological Storage of CO₂

中澳二氧化碳地质封存

© CO2CRC all rights reserved

What is EOR?

- EOR = Enhanced Oil Recovery
- As little as only 10-20% of the OOIP may be produced through primary recovery (natural pressure of the reservoir)
- Options include:
 - Waterflooding
 - Gas flooding (CO₂)
 - Thermal methods
 - Plus many others
- These can do two things to assist production:
 - Increase reservoir pressure
 - Change the properties to increase the mobility of the oil

Enhanced Oil Recovery

China Australia Geological Storage of CO₂

中澳二氧化碳地质封存

© CO2CRC all rights reserved

Worldwide EOR Production

- Production is currently 2.3 MM BOPD
- Represents 3.2% of the world's production
- Some projections reach 30 MM BOPD by year 2020
- CO₂ floods will be a major contributor

China Australia Geological Storage of CO₂

中澳二氧化碳地质封存

The Size of the Prize

- **Primary Production** **15% recovery**
- **Secondary Recovery recovery** **30%**
- **Enhanced Oil Recovery** **45% recovery**

China Australia Geological Storage of CO₂

EOR with CO₂

- Two types of processes of EOR using CO₂ injection,
 - **miscible**
 - **immiscible.**
- Early interest focused on immiscible displacement by carbonated water flooding. Most activity now, especially in the US is centred on miscible displacement.
- Miscible CO₂ flooding is best suited to light to medium gravity crudes and the immiscible process to heavy oils.
- This is because miscibility requires reservoir pressures above 8.3 kpa for light oils (>30API) and as high as 27.5 for heavy oils (<22.3 API)

China Australia Geological Storage of CO₂

中澳二氧化碳地质封存

CO₂ flooding

- But CO₂ is expensive and can be complex to handle.
- Water is cheap, easy and great for pressure maintenance.
- We need other reasons to use CO₂

China Australia Geological Storage of CO₂

中澳二氧化碳地质封存

CO₂/Oil Miscibility

- Above a certain pressure oil and super critical carbon dioxide become miscible that is they can completely mix with each other in all proportions forming a homogenous solution:

	Gravity	Miscibility pressure	
	° API	psia	mPa
Light oil	>30	1200	8.3
Medium oil	27-30	3000	20.7
Heavy Oil	<27	4000	27.5

These pressures increase as temperature increases above 120°F (49°C)

EOR through miscibility

- Miscibility is the mixing of two fluids to form a homogenous solution.

Miscible: Ethanol and water

Immiscible: Oil and water

Benefits of miscibility

- Reduction in viscosity
- Reduction in density (Swelling of the oil)
- Increased mobility
- Improved relative permeability

China Australia Geological Storage of CO₂

中澳二氧化碳地质封存

How it works

- Intermediate hydrocarbons vaporize into the flowing, mobile single-phase mixture
- 100% oil recovery is possible if injection lasts long enough. (although this is impractical)

Miscible EOR with CO₂

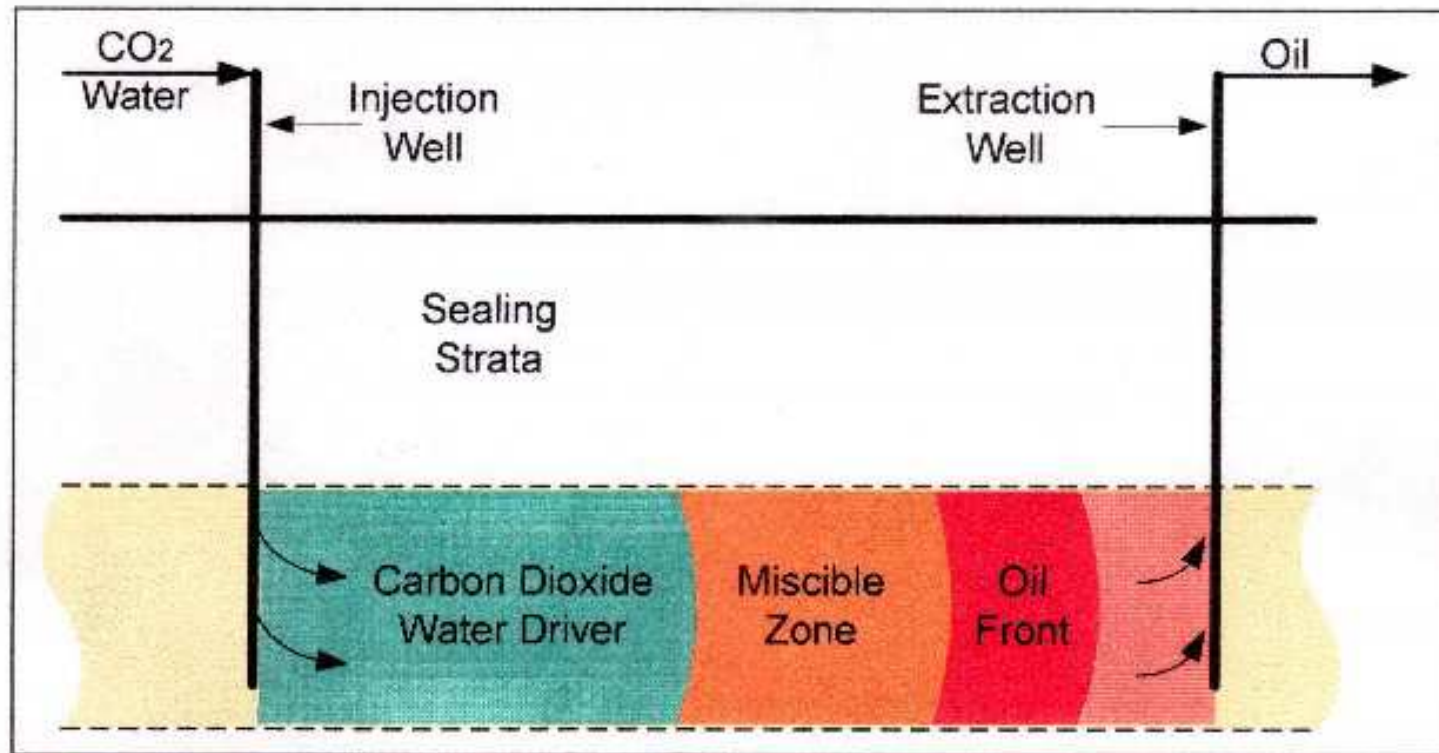

Figure 1. Miscible EOR

cags

China Australia Geological Storage of CO₂

中澳二氧化碳地质封存

© CO2CRC all rights reserved

Immiscible EOR

- CO₂ injected into to maintain pressure and drive the oil towards the producing well.
- However CO₂ is also highly soluble in crude oil. Dissolution will swell the oil, which will decrease its viscosity and also force water out of the pore spaces to allow increased drainage.

Figure 2. Immiscible EOR

This process can be very important in heavy oil fields such as are found in China and in Turkey

Miscible or Immiscible EOR

Miscible EOR	Immiscible EOR
Light to medium crude oils with API Gravities > 25° with high miscibility with CO2	Heavy to medium crudes, with API Gravities as low as 10° API
The crudes to have low concentration of aromatic (benzene ring) compounds	Having geological structures where oil 'pushing' from above will be useful
The reservoirs to have only moderate temperatures and are appropriate to 'flooding'	Access to significant amounts of CO2 that may or may not be 'clean'
Applicable for reservoirs in reasonable proximity to 'clean' CO2	Applicable where the extraction of oil is not an IMMEDIATE priority

Operational Concerns

- Miscible or immiscible (Minimum Miscibility Pressure)
- CO₂ source?
- Reservoir heterogeneity
- Fractures
- Gas breakthrough
- Infrastructure for processing/handling/separating
- Wax and Asphaltene build-up
- Corrosion

Weyburn CO₂ Project

- CO₂ Source: Dakota Gasification Company
- 95 mmscfd (5000 tonnes/day) injection rate
- CO₂ purity 95% (primary feed)
- Currently 26% recycle.

Main CO₂ pipeline enters Weyburn

EOR with CCS – Weyburn/Midale

Oil Production: ~ 28,000 bbl/day
(approximately 20,000 bbl/d more than would be produced without the CO₂ flood)

Objective: produce more oil (CO₂ storage secondary!)

CO₂ Storage: ~ 1.3 Mt/year
(approximately 13 Mt total)

China Australia Geological Storage of CO₂

中澳二氧化碳地质封存

Less than 100% of the CO₂, possibly as little as 26% is recovered in each cycle – therefore that percentage that is retained in the formation is stored.

Field Injection Options

- Continuous CO₂ or (CO₂ + Water)
- Water-Alternating-Gas (WAG)

cags

China Australia Geological Storage of CO₂

中澳二氧化碳地质封存

© CO2CRC all rights reserved

Field Injection Options

- **Continuous CO₂-Disadvantages**
 - Early CO₂ breakthrough
 - Poor areal efficiency
 - Poor vertical efficiency
 - Large injection volume of CO₂/ Significant recycling
- **WAG-Disadvantages**
 - Water sensitive formations impaired
 - Water injection decreases with time
 - Operational: Corrosion (producing wells)

CO₂ Storage in Oil Reservoirs:

- Replaces oil and gas volume produced
- Soluble in crude oil
 - (requires post production separation)
- Soluble in water (connate and/or waterflood)
 - (some recycling)
- Adsorption to some clay minerals
- Not economically viable today without EOR

China Australia Geological Storage of CO₂

中澳二氧化碳地质封存

EOR Summary

- CO₂: gas-like viscosity, liquid-like density
- High Density CO₂ (liquid or high-pressure super-critical) for larger stored mass.
- CO₂ is economic to increase oil production in basins where naturally occurring CO₂ reservoirs exist.
 - Numerous commercially successful miscible field applications
 - Few commercially successful immiscible field applications

Economic simulation of CO₂-EGR

- CO₂-EGR can add significant gains to a natural gas field depending on key variables such as:
 - CO₂ Injection timing
 - Existing CO₂ in the field
 - Additional HC recovery
 - Carbon penalty

cags

CO₂-EGR can add value

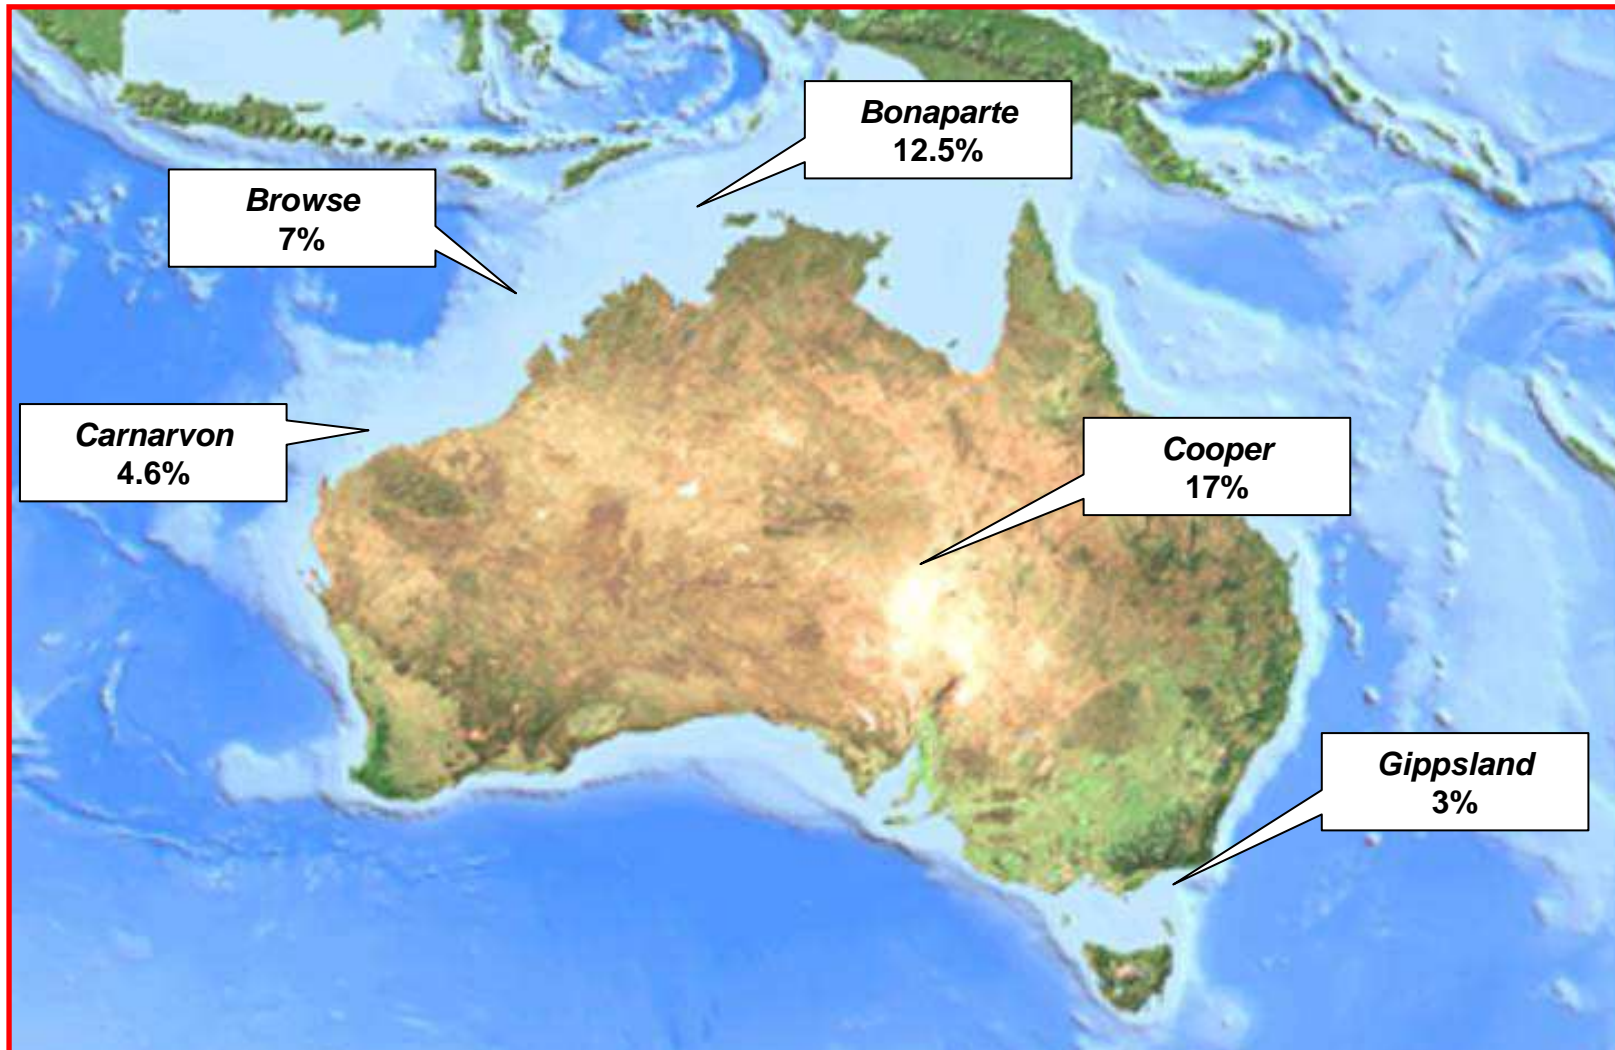

Optimising injection timing and other key variables can add significant value to a field

1. Primary depletion
 2. Injection at the start of production
 3. Injection during production
 4. Injection at the end of production
- Methane incremental production
 - Condensate incremental production
 - Overall CO₂ stored
 - NPV
